

## Exploring three interdisciplinary areas and the extent they overlap. Are they all part of the same larger domain?

BY THANASSIS TIROPANIS, WENDY HALL, JON CROWCROFT, NOSHIR CONTRACTOR, AND LEANDROS TASSIULAS

# Network Science, Web Science, and Internet Science

THE OBSERVATION OF patterns that characterize networks, from biological to technological and social, and the impact of the Web and the Internet on society and business have motivated interdisciplinary research to advance our understanding of these systems. Their study has been the subject of Network Science research for a number of years. However, more recently we have witnessed the emergence of two new interdisciplinary areas: Web Science and Internet Science.

Network Science can be traced to its mathematical origins dating back to Leonard Euler's seminal work on graph theory<sup>15</sup> in the 18<sup>th</sup> century and to its social scientific origins two centuries later by the psychiatrist

Jacob Moreno's<sup>25</sup> efforts to develop "sociometry." Soon thereafter, the mathematical framework offered by graph theory was also picked up by psychologists,<sup>2</sup> anthropologists,<sup>23</sup> and other social scientists to create an interdisciplinary called Social Networks. The interdisciplinary of Social Networks expanded even further toward the end of the 20<sup>th</sup> century with an explosion of interest in exploring networks in biological, physical, and technological systems. The term Network Science emerged as an interdisciplinary area that draws on disciplines such as physics, mathematics, computer science, biology, economics, and sociology to encompass networks that were not necessarily social.<sup>1,26,35</sup> The study of networks involves developing explanatory models to understand the emergence of networks, building predictive models to anticipate the evolution of networks, and constructing prescriptive models to optimize the outcomes of networks. One of the main tenets of Network Science is to identify common underpinning principles and laws that apply across very different networks and explore why in some cases those patterns vary. The Internet and the Web, given their spectacular growth and impact, are networks that have captured the imagination of many network scien-

### » key insights

- **Web Science and Internet Science aim to understand the evolution of the Web and the Internet respectively and to inform debates about their future. These goals lead to different priorities in their research agendas even though their communities overlap.**
- **Network Science aims to understand the evolution of networks regardless of where they emerge: the Internet as a network transforming and forwarding information among people and things, and the Web as a network of creation and collaboration.**
- **Given their intellectual complementarities, we propose sharing and harmonizing the data research infrastructures being developed across these three interdisciplinary communities.**

tists.<sup>13</sup> In addition, the emergence of online social networks and the potential to study online interactions on a massive, global scale hold the promise of further, potentially invaluable insights to network scientists on network evolution.<sup>24</sup>

**Web Science**<sup>6</sup> is an interdisciplinary area of much more recent vintage that studies the Web not only at the level of small technological innovations (micro level) but also as a phenomenon that affects societal and commercial activities globally (macro level); to a large extent, it can be considered the theory and practice of social machines on the Web. Social machines were conceptualized by Tim Berners-Lee in 1999 as artifacts where people do the creative work and machines intermediate.<sup>3</sup> Semantic Web and linked data technologies can provide the means for knowledge representation and reasoning and enable further support for social machines.<sup>20</sup>

Studying the Web and its impact requires an interdisciplinary approach that focuses not only on the technological level but also on the societal, political and commercial levels. Establishing the relationship between these levels, understanding how they influence each other, investigating potential underpinning laws and exploring ways to leverage this relationship in different domains of human activity is a large part of the Web Science research agenda. Web Science draws on disciplines that include the social sciences, such as anthropology, communication, economics, law, philosophy, political science, psychology,

and sociology as well as computer science and engineering. A major focus of the Web Science research agenda is to understand how the Web is evolving as a socio-technical phenomenon and how we can ensure it will continue to evolve and benefit society in the years to come.

**Internet Science.** The Internet has provided the infrastructure on which much of human activity has become heavily dependent. After only a few decades of Internet development it is self-evident that if the Internet became unavailable, the consequences for society, commerce, the economy, defense, and government would be highly disruptive. The success of the Internet has often been attributed to its distributed governance model, the principle of network neutrality, and its openness.<sup>14</sup> At the same time, concerns related to privacy, security, openness, and sustainability are raised and researched as they are often at the center of contestations on the Internet.<sup>11</sup> The Internet can be seen as an infrastructure, the social value of which must be safeguarded.<sup>18</sup> It is the infrastructure that enabled the evolution of the Web along with P2P applications, more recently the cloud, and, in the near future, the Internet of Things. It has been argued the infrastructural layer of the Internet and that of the Web must be kept separately to foster innovation.<sup>4</sup> A recent study<sup>7</sup> identified a number of principled directions along which the Internet needs to evolve; those include availability, inclusiveness, scalability, sustainability, openness,

security, privacy, and resilience. This motivates the need for multidisciplinary research on Internet Science that seeks to understand the psychological, sociological, and economic implications of the Internet's evolution along these principled directions. Hence, Internet Science is an emerging interdisciplinary area that brings together scientists in network engineering, computation, complexity, security, trust, mathematics, physics, sociology, economics, political sciences, and law. This approach is very well exemplified by the early Internet topology study.<sup>16</sup>

**Interdisciplinary relationships.** All three areas draw on a number of disciplines for the study, respectively, the nature and impact of the Web, the Internet and networks in general on government, business, people, devices, and the environment. However, each of them examines how those actors co-create and evolve in distinct, unique ways as shown on Figure 1. For Web Science it is the aspect of linking those actors and the content with which they interact making associations between them and interpreting them. For Internet Science it is the aspect of communication among actors and resources as processes that can shape information relay and transformation. For Network Science, it is the aspect of how these entities, when considered to be part of a network, exhibit certain characteristics and might adhere to underpinning laws that can help understand their evolution.

However, to understand better the

**Figure 1. Web, Internet, and Network Science aspects.**

similarities and differences between these areas and to establish the potential for synergies, a framework for a more detailed comparison is needed.

### A Comparison of Interdisciplinary Areas

It takes only a quick read through a short description of each of these interdisciplinary areas<sup>5,32,35</sup> for one to realize that, to a very large extent, they all draw from very similar sets of disciplines. Venn diagrams that have been used to illustrate the involvement of different disciplines in each area are indicative of this overlap. For example, psychology and economics are considered relevant to Network Science,<sup>29</sup> Internet Science,<sup>7</sup> and Web Science.<sup>20</sup> This can give rise to certain questions such as: “If there is so much overlap, aren’t these areas one and the same?” or “Would they all merge in the future?” Other questions include: “Which community is more relevant to my research?” or “What developments could we expect from each area in the future?” To explore those questions we propose a framework of examining those interdisciplinary areas, which includes looking at the way that these communities have formed, and the different languages of discourse that these communities have employed in their research.

**Community formation.** Although not all three interdisciplinary domains were established at the same time, one can argue that research in those areas dates back before their official starting date. At the same time, one can also argue there are differences in how communities around those domains emerged.

The formation of the Social Networks community can be traced back to a series of social network conferences that started in the 1970s<sup>17</sup> with an important conference in Dartmouth in 1975 that brought together sociologists, anthropologists, social psychologists, and mathematicians from the U.S. and Europe. This was followed by Lin Freeman’s launch of *Social Networks* in 1978, and Barry Wellman founding the International Network for Social Network Analysis (INSNA) in 1976 and its annual Sunbelt Social Networks conference in 1981. Beginning in the 1990s, the so-

**All three areas draw on a number of disciplines for the study, respectively, the nature and impact of the Web, the Internet and networks in general on government, business, people, devices, and the environment.**

cial scientists were joined by a large and growing influx of scholars from the physical and life sciences who began exploring networks in social systems. This effort was acknowledged and further catalyzed by the launch of annual Network Science (NetSci) conference in 2006, a major infusion of funding in 2008 from the Army Research Laboratory for the development of an interdisciplinary Network Science Collaborative Technology Alliance (NS-CTA), and the launch of *Network Science* in 2013. Clearly there was already a community in place, which engaged in interdisciplinary work long before those initiatives; one can argue a hybrid bottom-up and top-down approach is the community formation model that was followed for Network Science.

For the Web Science community, it was around 2006 when it was realized that understanding the impact of the Web was essential to safeguard its development in the future. The Web Science Research Initiative (WSRI) was established in 2006 and later developed into the Web Science Trust (WST) as part of the top-down approach to the formation of the Web Science community. The WSRI raised a banner for those who were engaged in research on the Web as a socio-technical phenomenon, including the social network research community. A similar community formation model was followed for Internet Science, where the European Network of Excellence in Network Science (EINS)<sup>8</sup> is one of the most significant activities to bring together the research community in this area. Areas such as privacy and network neutrality have been highlighted as priorities in the Internet Science agenda.

It can be argued the top-down model of community formation can accelerate research in emergent interdisciplinary areas but, in order to be successful, it requires a significant investment of resources from individuals, from research institutions, and from industry or government. Although the Web Science and the Internet Science communities were formed mostly in a top-down fashion, the sustainability of

a <http://www.internet-science.eu>

those communities was ensured by research funding from key research institutions, national research councils, the European Union, and significant effort by individuals.

**Use of a lingua franca.** Beyond community formation, there are differences in the language of discourse (the lingua franca) that is employed in each area. Network scientists initially shared graph theory as their lingua franca but have more recently employed models taken from physical processes (percolation, diffusion) and game theory<sup>13</sup> to describe processes on graphs. They have also moved from descriptive network metrics to the development of novel inferential techniques to test hypotheses about the evolution of a network based on various self-organizing mechanisms.<sup>27,28</sup> As a result, the use of graph theory is not necessarily the foundation for contemporary Network Science research. Further, there is use of complex systems analysis to deal with phase changes and discontinuities between different operating regimes; these are used to study why epidemic and pandemics spread globally. As a result, many Network Science publications are featured in journals such as *Nature*.

The Web Science community has not yet embraced a lingua franca per se but one can argue that an understanding of Web standards, technologies, and models (HTTP, XML, JavaScript, REST, models of communication, ontologies) and of frameworks of social theory are components of what could develop into a lingua franca. The W3C has been fostering a significant part of the discussion on Web protocols and their implications. A basic understanding of the evolution of the Web on both the micro and macro levels is the foundation for Web Science research.

Similar means of discourse are employed in the Internet Science community. For Internet Science, the components of the lingua franca include the set of Internet standards (RFCs) and associated commentary and implementation (or even C code) as in Stevens' books,<sup>30,31</sup> as well as the existence of de facto standard implementations of systems in open source. They also include a basic

understanding of the principles of Internet protocols, infrastructure (routers, links, AS topology), social science (preferential attachment models), law, and policy.

**Research methodologies.** In Network Science, research methodologies involve network modeling and network analysis<sup>9,10</sup> on networks that include, but are by no means restricted to, the Web and the Internet. In Internet Science, methodologies that employ measurements of engagement of Internet users with online resources and the Internet of Things are prevalent. In Web Science, mixed research methods that combine interpretative and positivist approaches are employed widely to understand the evolution of the Web based on online social network datasets, click-stream behaviour, and the use of the Web of data.

Beyond methodologies, the Web Science community is working on providing the Web Science Observatory,<sup>33,34</sup> a global distributed resource with datasets and analytic tools related to Web Science. Similarly, the EINS project is working on providing an evidence base for Internet Science research. And the Network Science community have a long tradition of making canonical network datasets available for use by the community along with network analysis software such as UCINET<sup>8</sup> and large-scale repositories of network data such as SNAP.<sup>22</sup>

Clearly there is an overlap in the research methodologies of these three areas:

- ▶ They draw on data gathered from social networks, infrastructures, sensors and the Internet of Things,
- ▶ They involve measurement, modelling, simulation, visualisation, hypothesis testing, interpretation and exploratory research, and
- ▶ They use analytical techniques to quantify properties of a network (abstract, virtual or real) as well as more qualitative techniques.

So far, there has been significant emphasis on the social sciences in Web Science, on both social science theories and methodologies in Network Science and on protocols and computer science in Internet Science. However, these foci will change in the

future and the research methods or data will continue to mingle between these three areas. For example, data on the Internet of Things might not remain exclusive to Internet Science since that data could be combined with data on human behavior on the Web from the Web Science perspective or to explore emergence and outcomes of the networks they enable from the Network Science point of view. Similarly, data on the behavior of users on the Web will be used to explore the use of bandwidth in the underlying Internet infrastructure. The different types of measurement point to the fact that often, part of the research, especially in the top-down-formed areas of Internet Science and Web Science, are associated to specific goals.

Given this shared pool of methods and data resources, each area employs mixed methods to leverage this pool in different ways according to their research agendas as illustrated in Figure 2. Those agendas are informed by different research goals.

**Research goals.** “Web Science is focused on how we could do things better, while Network Science is more focused on how things work;”<sup>36</sup> the “doing things better” refers to leveraging the potential of the Web and ensuring its continuing sustainability. Similar claims are made on behalf of Internet Science and Network Science. Although the use of the term ‘science’ relates to the systematic organization of knowledge and is not directly linked to goals, we argue that goals do play a role in the formation of these interdisciplinary areas and in shaping their research agendas, scientific contribution, and impact. In Web Science, the study of the Web itself is crucial,<sup>21</sup> as is safeguarding the Web and its evolution.<sup>19</sup> In Internet Science, the evolution and sustainability of the Internet and its services are central objectives; it is understood that tussles will always be the case on the Internet and that accommodating them is necessary in order to ensure its evolution.<sup>11</sup> It seems that in both Internet Science and Web Science applied research comes first but it should be informed by the development of a basic research program. In addition, neither

Web Science nor Internet Science is technology neutral; each one relies on specific protocols and standards. Further, one can argue that even the code that implements those standards embeds policy on which each respective community has reached some consensus. On the other hand, Network Science is technology agnostic and it overlaps only in part with Internet Science and Web Science, since it explores emergent structural patterns and flows on network structures be they social, biological, the Web, or the Internet. Finally, Web Science and Internet Science are both also engineering disciplines; they are about building better, stronger, more robust, efficient, and resilient systems. Network Science has been predominantly focused on understanding and describing emergent processes although, access to large datasets have increased interest in both predictive analytics to anticipate network changes and prescriptive analytics to optimize networks to accomplish certain desired goals. In essence, Network Science is aspiring to take insights from basic research to engineer better networks.<sup>12</sup>

**Comparisons.** Despite the differences between these areas in terms of the community formation models, lingua francas, and goals, many of the research methods they employ are common. This points to potential synergies on topics in which these areas overlap and the potential for mobilization within those communities on topics in which there is little or no overlap. Figure 3 shows such topics from each of these areas:

1. *Web Science:* The area of Web-based social media is one example of primarily Web Science research. Network aspects are not the exclusive part of this since social media research focuses on associations and interaction among people and social media resources.

2. *Internet Science:* Research on how the Internet of Things affects information collection and transformation is primarily Internet Science research that cannot rely exclusively on network research either.

3. *Network Science:* Transport networks provide an example of network science research that does not neces-

sarily relate to Internet or Web science.

4. *Web Science and Internet Science:* Network neutrality is an example that requires understanding of both Web and Internet technology and it does not necessarily draw primarily on net-

work science techniques.

5. *Internet Science and Network Science:* Content Delivery Networks can require network techniques for distribution prediction and optimization and, at the same time, understanding

**Figure 2. Network, Internet, and Web Science methodologies.**

**Figure 3. Research topics differentiating areas and overlaps.**

of how Internet protocols and people relate to shaping that demand.

6. *Network Science and Web Science*: Diffusion on social media such as Twitter is an example that relies on Web Science socio-technical research methods and, at the same time, on network analytic methods.

7. *Web Science, Internet Science and Network Science*: Research on trust online or on SOPA (Stop Online Piracy Act) and its side effects draw on all networks and on techniques that are aware of Web, and Internet protocols and code.

As the Web and the Internet continue to evolve it could be that some of these topics will shift.

## Conclusion

We provide a comparison among Network, Web, and Internet Science. We also propose a framework for comparing interdisciplinary areas based on their community formation, lingua francas, research methods and resources, and research goals. We can gain additional insights of the relationship among these areas by conducting co-author and co-citation analysis of publications within these areas and explore the extent to which these are distinct or merging interdisciplinary intellectual communities. Such an analysis would be even more meaningful as the related conferences and journals mature and as the similarities and differences among these areas potentially crystallize.

Both Internet Science and Web Science are technology-aware and their respective lingua francas include knowledge of the protocols and systems supporting the Internet and the Web, while Network Science is technology-agnostic. There are arguments in keeping the two layers of the Internet and the Web separate to foster innovation;<sup>4</sup> consequently, Internet Science and Web Science remain two distinct interdisciplinary areas given they have different goals, those of safeguarding the Internet and the Web, respectively. Network Science explores phenomena that include, but are not limited to, the Web or the Internet.

However, given the shared pool of mixed methods and datasets among these three interdisciplinary areas, there are compelling benefits for col-

laboration to harmonize and share resources; this should be a high priority for researchers and funding agencies.
